

Is it going to be a single page, slide show background with content window overlays atop the background?

The background hatch fading into the top of the menu/logo area is nice. Figure out something similar but more original

Something like this, but "finishes"

This design scales horribly on big screens, which designers are likely to have

I haven't spent time with resolution and scaling. My focus has been on backend. So maybe a dumb question, but does is it easier to design for larger resolution and scale down? I know mobile causes some issues. . . maybe a screen detect and have a simplified version for mob devices as opposed to fluid layout?

Fade in/out on this bar is nice, maybe use it for a different function

I feel like these sites always look better on lower resolution screens. Maybe have a 1080/1440 detect that allows us to fill in a bit of the dead space or scale everything up a %

needless "look how fancy we are" clutterly crap

Basically thinking of a much more simple version of this design. Can add features if it looks too bare bones after the framework/general design is done

these could actually be inset a little and not be such a huge element

Not sure about these buttons, they seem like too much. Find a different way to have additional options on the home page without presenting so much stuff to click on

Yeah, I've never understood the need for a duplicate nav bar at in the footer. Fixed floating nav bar in the the header then??

Again, I've been working on backend stuff, so setting up servers, db's, and writing API's. I'm just getting into this but I think one way to go about building the clean functionality that you're talking about is with a template engine (one option <http://jade-lang.com/>) and maybe an MVC controller like angular to handle DOM manipulation. Probably don't even need the controller though because I'm guessing it's going to be mostly static pages. Could probably just write all the dom manip with jquery and javascript.

Less text here, one row

onmouse event on each menu heading, jQuery incremental fade in of selections

find a method to cut the abruptness of loading a new page without making it feel like a flash website
